

The present invention relates to the discovery of novel insulin-releasing peptides in the skin secretions of amphibians and their potential use as stimulators of pancreatic beta cell function in the treatment of diabetes mellitus.

Amphibian skin contains two kinds of secretory glands. Mucous glands are distributed throughout the body, and their secretions mainly provide the moist coating necessary for cutaneous respiration. The granular glands, also known as serous or poison glands may be distributed or concentrated in certain areas of the body. The secretions from the granular glands of anurans (frogs and toads) have been shown to contain pharmacologically active substances ranging from simple amines such as norepinephrine and histamine to biologically active peptides, piperidine and steroid alkaloids, bufadienolides and tetrodotoxin [Bevins CL and Zasloff M 1990 Peptides from frog skin. *Annual Review of Biochemistry* 59 395-414; Erspamer V & Melchiorri P 1983 Neuroendocrine perspectives. pp. 37-104. Elsevier Science, Amsterdam]. These compounds are thought to play various roles, either in the regulation of physiological functions of the skin or in defence against predators or microorganisms [Barthalmus GT 1994 Amphibian biology. pp. 382-410. Beatty and Sons, Surrey.: Barra D and Simmaco M. 1995 Amphibian skin: a promising resource for antimicrobial peptides. *Trends In Biotechnology* 13 205-209].

During evolution some of these agents, or closely related daughter molecules, may have taken on distinct physiological roles in humans. It follows that pharmacologically active substances isolated from the skin secretions of frogs and toads may be useful for the treatment of human clinical disease such as diabetes mellitus.

The invention will now be demonstrated with reference to the following non-limiting examples and the accompanying figures wherein:

Figures 1 - 7 illustrate that semi-preparative C18 HPLC fractions of the skin secretions of various amphibians (*Agalychnis calcarifer*, *Agalychnis litodryas*,

Bombina variegata, *Phyllomedusa trinitatis*, *Rana palustris*, *Rana pipiens* and *Rana saharica*, respectively) stimulate insulin secretion from BRIN-BD11 cells. Legend: Effects of various semi-preparative C18 HPLC fractions of the respective specified crude venom on insulin secretion from BRIN-BD11 cells. Incubations were performed at 5.6mM glucose. Values are the mean \pm SEM for 3 separate observations. *P<0.01 and **P<0.001 compared with 5.6mM glucose alone.

Figure 8 illustrates the dependence of the stimulatory effects of 1653.2 Da purified peptide (peak 1.10) from *Agalychnis calcarifer* on intracellular pathways mediated by protein kinase A (forskolin), protein kinase C (PMA) or pertussis toxin-sensitive G-proteins. Legend: Acute effects of the 13 amino acid 1653.2 Da purified peptide (peak 1.10) from *Agalychnis calcarifer* on forskolin and PMA on insulin secretion from BRIN-BD11 cells cultured overnight in the absence (control) and presence of 25 μ M forskolin, 10 nM PMA or 0.1 μ g/ml pertussis toxin. Acute incubations were performed at 5.6 mM glucose. Values are the mean \pm SEM for 8 separate observations. ***P<0.001 compared with 5.6 mM glucose alone under same culture conditions. $^{\Delta\Delta\Delta}$ P< 0.001 compared with respective test reagent following control culture.

Figure 9 illustrates the dependence of the stimulatory effects of 1641.7 Da, 1662.6 Da, 1619.8 Da and 1650.5 Da purified peptides (peaks 21, 22, 23 and 24) from *Bombina variegata* on intracellular pathways mediated by protein kinase A (forskolin), protein kinase C (PMA) or pertussis toxin-sensitive G-proteins. Legend: Acute effects of 1641.7, 1662.6, 1619.8 and 1650.5 Da purified peptides (peaks 21, 22, 23 and 24) from *Bombina variegata* on forskolin and PMA on insulin secretion from BRIN-BD11 cells cultured overnight in the absence (control) and presence of 25 μ M forskolin, 10 nM PMA or 0.1 μ g/ml pertussis toxin. Acute incubations were performed at 5.6 mM glucose. Values are the mean \pm SEM for 8 separate observations. **P<0.001 compared with 5.6 mM glucose alone under same culture conditions. $^{\Delta}$ P< 0.001 compared with respective test reagent following control culture.

Figure 10 illustrates the dependence of the stimulatory effects of 4920.4 Da and 4801.2 Da purified peptides (peaks 5.1 and 5.4) from *Rana saharica* on intracellular pathways mediated by protein kinase A (forskolin), protein kinase C (PMA) or

pertussis toxin-sensitive G-proteins. Legend: Acute effects of 4920.4 and 4801.2 Da purified peptides (peaks 5.1 and 5.4) from *Rana saharica* on forskolin and PMA on insulin secretion from BRIN-BD11 cells cultured overnight in the absence (control) and presence of 25 μ M forskolin, 10 nM PMA or 0.1 μ g/ml pertussis toxin. Acute incubations were performed at 5.6 mM glucose. Values are the mean \pm SEM for 8 separate observations. ***P<0.001 compared with 5.6 mM glucose alone under same culture conditions. $^{\Delta\Delta}$ P< 0.001 compared with respective test reagent following control culture.

According to a first aspect of the invention there are provided various peptides, and their fragments, as stimulators of insulin secretion and pancreatic beta cell function.

Sequenncce nos. d and e show 62% sequence homology and sequence nos. c and i show 82% sequence homology. Sequence nos. m and n show 91% sequence homology and sequence nos. k and q show 67% sequence homology. Sequence nos. l, o and p show sequence homology – sequence nos. l and o show 84% sequence homology, o and p show 65% sequence homology and l and p show 58% sequence homology.

In a second aspect, the invention provides brevinins, dermaseptins and esculentins that stimulate insulin secretion by activation of physiological stimulus-sectreion coupling pathways.

In each of the first and second aspects, the invention includes similar fragemnts and such similar fragemnts are characterised in the present invention, by % identity to the sequences disclosed herei, as determined by algorothms commonly known to those skilled in the art. For example, multiple alignment of sequences may be performed using the ClustalW method of alignment (Thompson et al, 1994, Nucleic Acids Research, 22, pp4673-4680; Higgins & Sharp 1989 Cabios 5:151-153).

In a further aspect, the invention provides use of such peptides to stimulate insulin secretion and/or midfy blood glucose excursions.

EXAMPLE 1

Collection of skin secretions: Captive bred of *Agalychnis calcarifer*, *Agalychnis litodryas*, *Bombina variegata*, *Phyllomedusa trinitatis*, *Rana palustris*, *Rana pipiens* and *Rana saharica* were maintained *in terraria* at 24 °C with 12 h/12 h light/dark cycle and fed on crickets. The skin secretions were obtained from groups of four amphibians from each species by gentle electrical stimulation (4-ms pulse width, 50 Hz, 5 V) using platinum electrodes rubbed over the moistened dorsal skin surface for 10s. Secretions were washed off into a glass beaker, using deionised water. The resultant secretions were freeze dried in a Hetosicc 2.5 freeze dryer (Heto, UK). Approximately 50 mg, dry weight, of skin secretion was obtained for each species.

Purification of peptide: Lyophilized crude venom (20mg) from each species was dissolved in 0.12% trifluoroacetic acid/water (2ml) and 1 ml of it was chromatographed on a Vydac 218TP510 semi-preparative C-18 column (25 x 1cm, Hesperia, California, USA). The column was equilibrated with 0.12% (v/v) trifluoroacetic acid/water at a flow rate of 2ml/min. Using 0.1% (v/v) TFA in 70% acetonitrile/water, concentration of acetonitrile in the eluting solvent was raised to

80% (v/v) over 80 min using linear gradients. Absorbance was monitored at 214nm with collection of 2ml fractions. Fractions which showed major insulin releasing activity were pooled and rechromatographed using a Vydac 208TP54 analytical C-18 column (25 x 0.46 cm). The column was equilibrated with 0.12% (v/v) trifluoroacetic acid/water at a flow rate of 1ml/min. Using 0.1% (v/v) TFA in 70% acetonitrile/water, the concentration of acetonitrile in the eluting solvent was raised to 15% (v/v) over 5 min and to 80% (v/v) over 70 min using linear gradients. Absorbance was monitored at 214nm.

Culture of insulin-secreting cells: Clonal rat insulin-secreting BRIN-BD11 cells were cultured in RPMI-1640 tissue culture medium containing 10% (v/v) foetal calf serum, 1% (v/v) antibiotics (100 U/ml penicillin, 0.1 mg/ml streptomycin) and 11.1 mM glucose. The production and characterisation of BRIN-BD11 cells are described elsewhere [5]. Cells were maintained in sterile tissue culture flasks (Corning, Glass Works, UK) at 37 °C in an atmosphere of 5% CO₂ and 95% air using LEEC incubator (Laboratory Technical Engineering, Nottingham, UK). In three experimental series using purified peptides from *Agalychnis calcarifer*, *Bombina variegata* and *Rana saharica* cells were cultured overnight with 25 µM forskolin, 10 nM PMA or 0.1 µg/ml pertussis toxin prior to acute tests.

Acute insulin release studies: Insulin release from BRIN-BD11 cells was determined using cell monolayers [McClennaghan NH, Barnett CR, Ah-Sing E, Abdel-Wahab YH, O'Harte FP, Yoon TW, Swanston-Flatt SK and Flatt PR 1996 Characterization of a novel glucose-responsive insulin-secreting cell line, BRIN-BD11, produced by electrofusion. *Diabetes* 45 1132-1140]. The cells were harvested with the aid of trypsin/EDTA (Gibco), seeded into 24-multiwell plates (Nunc, Roskilde, Denmark) at a density of 1.5 x 10⁶ cells per well, and allowed to attach overnight. Prior to acute test, cells were preincubated for 40 min at 37 °C in a 1.0 ml Krebs Ringer bicarbonate buffer (115 mM NaCl, 4.7 mM KCl, 1.28 mM CaCl₂, 1.2 mM KH₂PO₄, 1.2 mM MgSO₄, 10 mM NaHCO₃, 5 g/l bovine serum albumin, pH 7.4) supplemented with 1.1 mM glucose. Test incubations were performed for 20 min at 37 °C using the same buffer supplemented with 5.6 mM glucose in the absence (control) and presence of various venom fractions, peaks (equivalent to approx. 25 µl dried HPLC fraction) or test agents as indicated in the Figures. Cell viability after 20 min test incubations was

assessed by modified neutral red assay [Hunt SM, Chrzanowska C, Barnnett CR, Brand HN and Fawell JK 1987 A comparison of in vitro cytotoxicity assays and their application to water samples. *Alternatives to Laboratory Animals* 15 20-29]. After incubation, aliquots of buffer were removed and stored at -20 °C for insulin radiomimmunoassay [Flatt PR. and Bailey CJ 1981 Abnormal plasma glucose and insulin responses in heterozygous lean (ob/+) mice. *Diabetologia* 20 573-577].

Molecular mass determination: The molecular masses of the purified individual non-toxic peaks exhibiting insulin releasing activity were determined using Matrix Assisted Laser Desorption Ionisation-Time of Flight (MALDI-TOF) mass spectrometry. Electrospray Ionisation quadripole ion-trap Mass Spectrometry (ESI-MS) was used for *Agalychnis calcarifer*, *Bombina variegata*, *Rana pipiens* and *Rana saharica*. Masses were recorded and compared with theoretical values calculated by the peptide calculator, a computer software package.

Depyroglutamation: Where necessary (*Bombina variegata*), pyroglutamate at the N-terminal was removed by adding 25 µl of pyroglutamate aminopeptidase preparation (50mM Na₂HPO₄, 10mM β-mercaptoethanol, 1 mM dithiothreitol, and 1mM EDTA adjusted to pH 7.3 with H₃HPO₄) containing 0.4 mg/ml pyroglutamate aminopeptidase to 100µl of the lyophilised peptide. The reaction mix was incubated for 2 hours at 37 °C and then stored at -20 °C for subsequent amino acid determination by Edman degradation.

Structural analysis by automated Edman degradation: The primary structures of the purified peptides were determined by automated Edman degradation, using an Applied Biosystems Procise 491 microsequencer. Standard operating procedures were used (Applied Biosystems Model 491 Protein Sequencers Users Manual). The limit for detection of phenylthiohydantoin amino acids was 0.2 pmol. The primary structures were compared with those deposited in the SWISSPROTTM database.

Statistical analysis: Results are expressed as mean ± S.E.M. Values were compared using Student's unpaired t-test. Groups of data were considered to be significantly different if P<0.05.

Results

Isolation, mass spectrometry and sequence analysis of insulin-releasing peptides:

Skin secretions from the various amphibian species were purified by HPLC, yielding in each case multiple fractions that were subsequently screened for in vitro biological activity using BRIN-BD11 cells. The insulin-releasing profiles of peaks emerging from the primary HPLC separation are illustrated for *Agalychnis calcarifer*, *Agalychnis litodryas*, *Bombina variegata*, *Phyllomedusa trinitatis*, *Rana palustris*, *Rana pipiens* and *Rana saharica* in Figs. 1-7, respectively.

The major peaks of insulin-releasing activity were subjected to further HPLC purification steps, giving rise ultimately to the isolation of pure peptides with proven insulinotropic activity (Tables 1-7). Where sufficient sample was available, molecular masses and either partial or complete sequences were determined for each peptide as summarised for the various amphibian species in Tables 1-7. In instances where a complete sequence was obtained, the theoretical (calculated) molecular masses of the peptides were shown to correspond closely to the experimental masses. This indicates the absence of any post-translational modification of constituent amino acids, such as phosphorylation, sulphation or glycation.

Six of the insulinotropic peptides have proved to be established structures. Peak 4.1 from *Rana pipiens* was identical to pipinin-1, peak 23 from *Bombina variegata* to bombesin, peak 2.10 from *Phyllomedusa trinitatis* to dermaseptin BIV precursor and peaks 5.4, 6.5 and 8.3 from *Rana saharica* matched Esculentin-1B, Brevinin-2EC and Brevinin-1E respectively. With these few exceptions, all other insulin-releasing peptides were novel structures as established using the SWISSPROT™ database. Even the functional observations with pipinin-1, dermaseptin BIV precursor esculetin-1B and brevinin-2EC and 1E were novel as these were totally unsuspected insulin releasing peptides.

Modest similarity existed between some of the isolated insulin-releasing peptides and amphibian antimicrobial peptides that are unsuspected insulin secretagogues such as brevinin, dermaseptin, Rugosin A and tryptophyllin. However, unlike the latter agents, no evidence was obtained of cell lysis or a toxic action that might account for insulin secretion. Thus the peptides reported herein appear to act through physiological mammalian processes controlling exocytosis of insulin.

To support this view, further studies were carried out using purified peptides from *Agalychnis calcarifer*, *Bombina variegata* and *Rana saharica* to examine cellular

mechanisms underlying the stimulation of insulin secretion. The stimulatory effects of the 1653.2 Da peptide (peak 1.10) from *Agalychnis calcarifer* (Figure 8) and 1641.7, 1662.6, 1619.8 and 1650.5 Da peptides (peaks 21, 22, 23 and 24 respectively) from *Bombina variegata* (Figure 9) were abolished in cells cultured overnight with forskolin to desensitise the cyclic AMP-protein kinase A pathway. Overnight culture with PMA or pertussis toxin did not affect the insulin-releasing ability of the peptides, suggesting lack of involvement of protein kinase C or G-protein dependent pathways. Overnight culture with forskolin or PMA resulted in the abolition of the acute stimulatory effects of forskolin or PMA, respectively (Figures 8 and 9). Interestingly, the insulin-releasing action of the 1653.2 Da peptide from *Agalychnis calcarifer* and peaks 21, 22, 23 and 24 from *Bombina variegata* were not affected by 50 μ M verapamil and were clearly evident in cells depolarised with 30 mM KCl (Tables 8 and 9).

Table 8 Effects of the 13 amino acid peptide peak (peak 1.10) from *Agalychnis calcarifer* on insulin secretion from BRIN-BD11 cells in the presence of verapamil or a depolarising K⁺ concentration.

KCl (30mM)	5.33 ± 0.38	13.68 ± 1.42	13.69 ± 1.43	15.21 ± 1.43	15.35 ± 0.41 ^{ΔΔΔ} ^{***}

Acute incubations were performed at 5.6 mM glucose. Values are mean ± SEM for 8 separate observations. *P<0.05 and ***P<0.001 compared with control, ^{ΔΔ}P<0.01 and ^{ΔΔΔ}P<0.001 compared with no addition.

The stimulatory effects of the 4920.4 and 4801.2 Da peptides (peaks 5.1 and 5.4) from *Rana saharica* were abolished in cells cultured overnight with forskolin, PMA or pertussis toxin (Figure 10) indicating the involvement of both protein kinase A and C and pertussis toxin-sensitive G-protein in their stimulatory actions. As shown in Table 10, the insulin releasing actions of the isolated peptides were not inhibited by the calcium channel blocker verapamil. Stimulatory effects on insulin secretion were also clearly evident in cells depolarised by 30 mM KCl.

Table 10 Effects of peaks 5.1 and 5.4 from *Rana saharica* on insulin secretion from BRIN-BD11 cells in the presence of verapamil or a depolarising K⁺ concentration.

Addition	Insulin secretion (ng/10 ⁶ cells/20 min)		
	Control	Peak 5.1	Peak 5.4
None	1.69 ± 0.17	2.96 ± 0.32***	2.89 ± 0.19***
Verapamil (50µM)	1.74 ± 0.17	2.88 ± 0.28***	2.79 ± 0.10***
KCl (30mM)	5.33 ± 0.38 ^{ΔΔΔ}	10.11 ± 0.81 ^{ΔΔΔ} ^{***}	11.84 ± 0.98 ^{ΔΔΔ} ^{***}

Acute incubations were performed at 5.6 mM glucose. Values are mean ± SEM for 8 separate observations. ***P<0.001 compared with control, ^{ΔΔΔ}P<0.001 compared with no addition.

Discussion

This research describes for the first time the isolation and characterisation of peptides with insulin-releasing activity from the skin secretions of *Agalychnis calcarifer*, *Agalychnis litodryas*, *Bombina variegata*, *Phyllomedusa trinitatis*, *Rana palustris*, *Rana pipiens* and *Rana saharica*. It is notable that this work has not only uncovered a

diverse range of novel peptides structures but it has also revealed that the skin secretions from each amphibian species studied represents an unsuspected and rich source of peptides capable of stimulating physiological insulin secretion from mammalian pancreatic beta cells.

The insulin output induced by amphibian peptides is approximately equivalent to that induced by established mammalian gut peptides, GLP-1, GIP or CCK-8 [Gault VA, O'Harte FPM, Harriott P, Mooney MH, Green, BD and Flatt PR 2003 Effects of the novel (Pro³) GIP antagonist and exendin (9-39) amide on GIP- and GLP-1-induced cyclic AMP generation, insulin secretion and postprandial insulin release in obese diabetic (ob/ob) mice: evidence that GIP is the major physiological incretin.

Diabetologia 46 222-230; O'Harte FPM, Abdel-Wahab YH, Conlon JM and Flatt PR 1998 Glycation of glucagon-like peptide-1(7-36)amide: characterization and impaired action on rat insulin secreting cells. *Diabetologia* 41 1187-1193; Abdel-Wahab YH, O'Harte FPM, Mooney MH, Conlon JM and Flatt PR 1999 N-terminal glycation of cholecystokinin-8 abolishes its insulinotropic action on clonal pancreatic B-cells.

Biochimica et Biophysica Acta 1452 60-67]. This indicates that the amphibian peptides isolated are at least as capable as physiological mammalian hormones in stimulating insulin secretion. It is also clear that these peptides may also trigger insulin secretion and have other beneficial actions on beta cells which involve novel secretory pathways as suggested by studies using peak 1.10 from *Agalychnis calcarifer* and peaks 21, 22, 23 and 24 from *Bombina variegata*. In these cases the secretagogues appeared to be mediated through both protein kinase A and G-protein independent pathways. In the case of peptides isolated from *Rana saharica* (peaks 5.1 and 5.4), the stimulatory effects were also independent of pathways triggered by protein kinase C.

It is apparent from the insulin stimulatory effects that specific receptors must exist for these amphibian peptides on mammalian insulin-secreting beta cells. This gives rise to two major and highly novel non-exclusive possibilities. The first is that these insulin-releasing amphibian peptides have homologous or closely related mammalian counter-parts.

The second important possibility arising from this research is that the novel amphibian peptides described in Tables 1-7, or fragments thereof may offer a therapeutically useful means of treating insulin secretory dysfunction and other beta cell disturbances typical of diabetes in humans. Diabetes is predicted to reach epidemic proportions throughout the world in the next 20 years and current treatments do not restore normal glucose homeostasis, therein resulting in debilitating diabetic complications and premature death. Amphibian peptides may therefore be a useful addition to the therapeutic arsenal for use either alone or in combination with other agents to improve diabetes control and decrease the risk of associated complications.
